The Role of Repeated Interactions, Self-Enforcing Agreements and Relational [Sub]Contracting: Evidence from California Highway Procurement Auctions

Ricard Gil and Justin Marion
University of California, Santa Cruz*

October 2009

Abstract

We empirically examine the impact of relationships between contractors and subcontractors on firm pricing and entry decisions in the California highway procurement market using data from auctions conducted by the California Department of Transportation. Relationships in this market are valuable if they mitigate potential hold-up problems and incentives for ex post renegotiation due to contractual incompleteness. An important characteristic of informal contracts are that they must be self-enforcing, so that the value of relationships between firms and suppliers depend on the extent of possibilities for future interaction. We construct measures of the stock of contractors' prior interactions with relevant subcontractors and find that a larger stock of relationships leads to lower bids and a greater likelihood of entry. Importantly, this relationship does not hold in periods of time and areas with little future contract volume, suggesting that the self-enforcement mechanism is crucial in providing value for informal contracts.

1 Introduction

Relational contracting has long played an important role in the interaction between firms and their suppliers. The close relationships that firms have with their suppliers allow them to enact implicit contracts, obtaining first-best outcomes not achievable otherwise through formal contracts. In many circumstances it may be prohibitively expensive to completely specify in advance all relevant contingencies and product attributes to the transaction at hand. It is in these cases that relational contracting proves most useful since it helps a firm and its supplier respond to unforeseen circumstances when needed or induces the supplier to provide the informally agreed optimal product quality when the attributes of the supplied product are not verifiable to a third party.

There exists a growing empirical literature that establishes the prevalence of such informal contracts and their role in vertical relations as well as the type of formal contracts chosen between parties in the presence of long-standing relational contracts.[1] As noted by Bull (1987), Klein (1996) and others, an important factor characterizing a relational contract is that it cannot be enforced by a third party and therefore must be self-enforcing. The standard relational contract specifies an action that the supplier needs to undertake at the risk of losing all future business. When the value of deviating from the action in the implicit contract exceeds the present value of continuing the relationship, the relationship is no longer self-enforcing and ceases to have value in solving the information asymmetry problems that formal contracting could not address, such as contractual incompleteness, moral hazard, or holdup. Therefore, the current value of the relationship depends on the value of future business between the two parties.

In this paper, we empirically examine the effect of relationships between contractors and subcontractors in the highway construction market on bidding, auction participation, and subcontractor choices. In contrast to the prior empirical relational contracting literature, we empirically evaluate the role of the continuation value of the contractor-subcontractor relationship. The highway construction market is a particularly appealing setting to study this issue. In many traditional settings, the observed continuation value is endogenous to the productivity of the firm-supplier match, as more successful relationships lead to a higher volume of future business. This leads to a reverse causality problem, as the measured volume of future business will therefore be related to lower prices in the current period for reasons unrelated to the enforcement of informal contracts.

---

[1]Early examples of this empirical work include Macaulay (1963) or Asanuma (1989).

In contrast, the arrival rate of public highway construction projects is driven by transportation needs and is likely orthogonal to the productivity of the contractor-subcontractor match.

Most of the existing empirical literature in this area measures relationships by the stock of prior interactions between a firm and its supplier. While this does not directly measure continuation value, it may proxy for the expected future value of the relationship if a regularly used supplier can expect to be utilized by the firm in the future. However, prior relationships may also have value through improving relationship specific productivity unrelated to contracting, such as by mitigating coordination costs and enhancing learning by doing.[2] Therefore, it is useful to more directly measure both the stock of prior interactions and the continuation value of the relationship simultaneously.

We begin by building a simple descriptive model where projects are comprised of two tasks. A firm will produce a task by itself and subcontract the other task to a subcontractor. When subcontracting, bidders choose a subcontractor depending on the subcontractor specific coordination costs and the value of their future relationship. Whereas past interactions with a subcontractor diminish current coordination costs, future interactions deter subcontractors from engaging in moral hazard behavior and therefore enhance the value of present activities. We argue that since contractors choose their subcontractors according to their task production costs, coordination costs, and *ex post* renegotiation costs, prior and future interactions play an important role in their decisions. We then derive testable implications regarding the nature of subcontracting decisions and take these implications to the data.

We evaluate the empirical validity of these implications using data from 5,120 highway procurement auctions conducted by the California Department of Transportation (Caltrans) between May 1996 and October 2005. When submitting a bid in this market, firms must list the significant subcontractors they intend to use on the project up for bid. Overall, the data consist of 26,125 bids from 1,735 contractors of which 805 win at least one contract. These bids specify roughly 2,900 unique subcontractors. We therefore are able to measure the stock of relationships a firm has with its subcontractors over time and across markets.

We find that greater stocks of prior relationships are associated with lower bids by firms, as well as a greater likelihood of auction entry. This finding is robust to different measures of the

---

[2]Kellogg (2008) empirically estimates the gains in firm-specific productivity from past repeated interactions for oil well drilling in Texas.

stock of prior relationships. Furthermore, firms are more likely to use subcontractors that they have worked with in the past.

The most important result of the paper is that the effects of relationships on bidding, entry, and subcontractor utilization depend on the extent of future business. We interact prior relationships with the number and dollar value of upcoming contracts within the geographic market. If no contracts are up for bid within the following year, the value of the stock of prior relationships on bidding and entry is statistically indistinguishable from zero. However, the greater is the extent of future business, the more prior subcontractor relationships lower the bid and raise the likelihood of entry. Importantly, only upcoming projects occurring within one year matter, which is consistent both with firms having better information regarding these projects and with discounting.

The paper is organized as follows. Next, we describe the relevant literature and specify what is the contribution of this paper within it. Section 3 describes the institutional details and section 4 presents our toy model that serves as theoretical framework. In this section, we use important institutional characteristics of the California Highway procurement sector to build up a simple model that resembles reality as much as possible and yields testable implications. In section 5, we describe the data at use and in section 6 we take our testable implications to the data. Section 6 also presents and discuss the methodology used in this paper and the empirical challenges that we encountered. Section 7 concludes.

2 Literature Review

As this paper empirically focuses on the consequences of repeated interactions and long-standing relationships on firm performance in California highway procurement contracts, we believe that this paper builds on and contributes to two strands of the literature. These are the literature on implicit and relational contracting and the literature that studies procurement and construction contracts as a special type of business.

2.1 Literature on Implicit and Relational Contracting

The role and importance of informal agreements is sometimes minimized by the large existing literature on formal contracting. Despite this, the nature of informal agreements together with the existence of implicit and relational contracting has been the subject of study of many for some time now. Klein and Leffler (1981) is among the earliest research on this topic followed by

others such as Bull (1987), Klein and Murphy (1988), Baker, Gibbons and Murphy (1994), Klein (1996) and more recently Board (2008) and Halac (2008). This literature studies the emergence of informal contracting when formal contracting may yield suboptimal outcomes. This set of theories emphasizes two main points. First, informal agreements will only emerge when they improve on the result of formal agreements, and second that their sustainability hinges on the capacity of participating parties to self-enforce these agreements leveraging the gains derived from future interactions between them.

The appeal of this idea has found applications in many different scenarios and as a consequence a literature surrounding the idea of future interactions sustaining informal agreements has developed. Some examples of these applications in this growing literature have been into topics as diverse as subjective pay performance (Baker, Gibbons and Murphy (1994)), quality provision (Klein and Leffler (1981)), the boundaries of the firm (Baker, Gibbons and Murphy (2002)) and procurement contracting (Calzolari and Spagnolo (2009)), and industries such as oil drilling (Corts and Singh (2004)), dry cleaning (Gil and Hartmann (2009)) or movies (Gil (2009)).

2.2 Literature on Procurement and Construction Contracts

Our paper also contributes to a more applied literature that documents the allocation of procurement contracts and in particular procurement of construction contracts. Examples of the former type are Guasch, Laffont and Straub (2008) where they examine the contractual adjustments of procurement contracts for utility concessions in a group of Latin American countries. Examples of the latter are Bajari and Tadelis (2001) and (2006), Bajari, McMillan and Tadelis (2008) and Bajari and Lewis (2009) where they examine theoretically and empirically the procurement of construction contracts. In general, these analyses ignore the fact that bidders in these auctions have ongoing relationships with the public agency and reputations that leave room for some degree of *ex post* adjustment. Similarly, the subcontracting of parts of the conceded utility contract tends to be unobserved by the econometrician and therefore its analysis omitted. Our paper focuses on these two exact components that have been ignored previously and hopes to shed light on the role of past and (expected) future repeated interactions in procurement.

A number of prior papers have also examined the California highway procurement auctions. In particular, Bajari, Houghton and Tadelis (2006) examine the role of incomplete contracts and ex post adjustments, and Krasnokutskaya (2003) estimates a structural auction model in the presence

of unobserved heterogeneity. There has been also a number of papers examining the effect of preferential programs in these auctions on auction participation and bidding behavior. Examples of these are Krasnokutskaya and Seim (2005), and Marion (2007, 2009). Our paper here differs from these and others in that it focuses on the subcontracting strategies of the contractors bidding for these highway construction projects and estimates the consequences of repeated interactions in contractor performance in these auctions.

We also need to acknowledge, and differentiate from ours, the contribution of two recent papers that study closely related topics to ours. Miller (2008) estimates the cost implications of contractual incompleteness in subcontracting decisions for a set of bridge construction contracts procured by the California Department of Transportation. Kellogg (2008) empirically examines the impact of repeated past interactions on the productivity of well drilling in Texas. Our paper differs from these two papers in that we focus on the role of future contracting possibilities to mitigate moral hazard problems and our empirical findings demonstrate that in the setting of California procurement auctions even though past repeated interactions are correlated with lower bids it is the continuation value of ongoing relationships that drives posted bids down.

Finally, this paper also relates to an economic literature that studies the construction industry for its unique organization of production. In particular, we highlight the contributions of Eccles (1981), and González, Arruñada and Fernández (1998) and (2000). The first documents the loose nature of the boundaries of the firm that appear to sustain transactions in this industry, while the latter two focus on the fragmentation of this sector and how specialization may lead firms to rely on subcontracting and outsourcing more often than similar firms in other industries. Our paper adds to this literature in that we examine a channel through which contractors may benefit of their subcontracting strategies and provide evidence on how repeated subcontracting may enhance firm performance.

3   Institutional Details: Bidding on California Highway Auctions

The California Department of Transportation (Caltrans) awards road construction and repair contracts through sealed-bid first-price auctions. Potential bidders are solicited through a newsletter that details the bid letting date and the details of the project.[3] A firm can bid on any project for

---

[3]Calzolari and Spagnolo (2009) show that when relational contracting between government and main contractor is valuable to solve moral hazard problems, the government may find optimal to screen contractors ex-ante and reduce the number of potential bidders so that the continuation value of relationships increases.

which it has been prequalified to do the specified category of work; this prequalification is based on the firm's equipment, training, licensing, and past work history. The engineer provides a list of the items required to complete the project and the quantities of each item.[4] The bidder provides a unit price for each item, and its bid is based on the total cost of all the item quantities and prices.

In its bid, the firm must list each subcontractor whose work accounts for at least 0.5 percent or $10,000, whichever is greater, of the contract value. Each subcontractor must be prequalified to do the listed work. Following existing regulation, at most 40 percent of a project can be subcontracted out. The other important restriction regarding subcontracting that applied through much of the period of our study regards affirmative action. Until 1998 for contracts using state funds and 2006 for federally funded contracts, contractors were often required to award a percentage of contract dollars to Disadvantaged Business Enterprises (DBEs), subcontractors owned by minorities and women.

While Caltrans attempts *ex ante* to specify the relevant details of the contract, unforeseen contingencies often arise after contract award (see Bajari et al, 2006). These changes to project specifications many times lead to costly renegotiation between the contractor and Caltrans. While we do not have direct evidence, these change orders likely also alter the scope or scale of the subcontractors' tasks as well in ways difficult to specify *ex ante*.

4   Theoretical Framework

In this section, we present a toy model to provide structure on how contractors may decide on their subcontracting strategies. We intend this to be the source of testable implications that we can take to the data regarding the relationship between a contractor's bidding behavior and its relational contracts with the available subcontractors. For this reason, we define the different costs incurred by both parties in the process and the timing of actions until the contractor posts its bid in the procurement auction.

---

[4]The item prices are used when relatively small differences arise between the quantity of an item the engineer predicts will be required and how much is actually required. When large differences between project specifications and actual required work occur, a potentially costly renegotiation of contract terms is undertaken. (Bajari et al, 2006)

4.1 Introduction of the Model

We present a static model that has intertemporal implications. In this model, the government procures a project in any given period with a probability p. Once the announcement is done in period t, a contractor i, within all possible I contractors, considers submitting a bid for a project k in period t. Projects are allocated by the government using first-price sealed-bid auctions.

For simplicity we assume that every project is comprised of two tasks. We simplify the problem at hand further by assuming that one of the two tasks (task 1) is required to be conducted by the contractor itself, consistent with the institutional details of this market. The other task (task 2) may be outsourced to a subcontractor j (out of the J available subcontractors).[5] Let the cost of completing tasks 1 by contractor i be given by c_{1kit}, while the cost of a subcontractor j to produce task 2 in period t is c_{2kjt}.

If a subcontractor j is hired to complete task 2, a coordination cost $\gamma_{ijkt}(e, n)$ is incurred that depends on effort e exerted *ex post* by subcontractor j. This effort is non-contractible because it cannot be observed ex-post by a third party. The coordination cost also depends on n which is the number of past interactions between contractor i and subcontractor j. We assume, not surprisingly, that coordination cost is lower with higher levels of effort and higher number of past interactions (learning by doing), that is, $\frac{\delta\gamma}{\delta e} < 0$ and $\frac{\delta\gamma}{\delta n} < 0$. These coordination costs vary across contractor-subcontractor match depending on their location and the location of project k as well as the number of times that they have actually worked together in a project in the past. To switch *ex post* from the initially chosen subcontractor j to another subcontractor $-j$, the contractor incurs a switching cost ϕ_{i-jtk}.

4.2 Timing of Actions and Solution by Backward Induction

The timing of actions and interactions between agents is represented in Figure 1. In period 0, all participating I contractors learn their costs to produce project k and the costs associated with hiring each subcontractor, including the direct construction cost as well as the coordination and *ex post* switching transaction costs specific to each contractor-subcontractor match. This means that we assume perfect symmetric information between participating contractors and subcontractors.

---

[5]This assumption could be extended easily to situations where the contractor is allowed to outsource all tasks or required to outsource a specific task. This is sometimes the case when particular expertise is required for a given task.

In period 1, contractor i decides what subcontractor j to use for task 2. At this point, contractor i compares all available subcontractors by their costs of producing task 2, $c_{2.kt}$, and her coordination costs with each of them, $\gamma_{i.kt}(e, n)$, taking as given the (unobservable and non-contractible) effort optimally exerted by the subcontractor.

In period 2, contractor i and subcontractor j bargain over the price subcontractor j will receive for its performance of task 2. To simplify our analysis, we assume that all *ex ante* bargaining power is on the contractor side due to competition between subcontractors[6] (at this stage subcontractors may appear on multiple bids for a same project). To this extent, the total cost of contractor i of dealing with subcontractor j will be $\gamma_{ijkt}(e, n) + c_{2jkt}$ plus some economic rent captured by subcontractor j due to its cost advantage over the second cheapest subcontractor that we call z.[7] In period 3, the contractor observes all her costs for project k and posts her bid given all outcomes occurred in the previous periods.

In period 4, the winner of the auction is determined. If the contractor has won, it now must deal with possible moral hazard from the subcontractor side. *Ex post*, the subcontractor may not provide the optimal amount of effort e expected by the contractor. This may cause delays and eventually extra compensation for the subcontractor on labor and capital costs. These extra costs would eat up part of the contractor profits, and therefore it is in her best interest to provide incentives to the subcontractor to exert the optimal amount of effort. The contractor could contract with another subcontractor $-j$ to finish the job but we assume that there exists an *ex post* switching transaction cost ϕ_{i-jtk} that keeps her locked into this relation and allows the subcontractor to hold her up.

4.2.1 Period 4: The Moral Hazard Problem of the Subcontractor

We now solve the model through backward induction. Once contractor i wins the auction for project k, it must deliver the project at the quality and time agreed with the buyer. To do this, it relies on the performance of the subcontractor j through the coordination cost $\gamma_{ijkt}(e, n)$. Assume for simplicity that subcontractor effort e can take two possible values, $e = \{e^*, 0\}$. This effort

---

[6]Subcontractors are not receiving zero profit. They will receive the difference between their costs and the cost of the second cheapest alternative subcontractor.

[7]In our toy model, we assume that subcontractors do not have deep pockets and therefore cannot "bid" a lower amount than their costs to contract with contractor i in project k.

cannot be contracted upon *ex ante* because it is not observable to third parties, but the contractor can observe it. The coordination costs will be higher if $e = 0$ such that

$$\gamma_{ijtk}(0, n) > \gamma_{ijtk}(e^*, n).$$

Due to the switching cost ϕ_{i-jkt}, the subcontractor can hold-up the contractor by demanding additional payment to provide ex-post the desired effort level e^*. In this case, the contractor i will hold-up subcontractor j as long as

$$\phi_{i-jkt} \geq \gamma_{ijtk}(0, n) - \gamma_{ijtk}(e^*, n)$$

or, in other words, the maximum amount that the subcontractor can hold up the contractor is the amount of the switching cost.

To solve the contractual incompleteness problem, the contractor can leverage the value of future interactions. Let us define V the expected present discounted value of future relationships for subcontractor j of its future interactions with contractor i such that

$$V(t') = \sum_{t=t'}^{\infty} (p\delta)^t [\Delta c_t + \sum_{t=t'}^{t} \Delta\gamma_{ijtk}(e, n(t))] = \sum_{t=t'}^{\infty} (p\delta)^t [z_t]$$

where t' is the current period, δ is the discount rate and p is the probability that the government will procure a new project in any given future period and therefore that contractor i and subcontractor j will interact in any given period in the future.[8] The value of future interactions also depends on z_t, the economic rent appropriated by the subcontractor and basically the cost difference between subcontractor j and the second cheapest subcontractor. As mentioned above, z_t is composed by the difference in materials cost and the difference between coordination costs acquired over time through repeated past interactions and learning by doing. If subcontractor j is not the cheapest subcontractor for the project procured, z_t will take value 0.

The contractor will then offer an informal contract to the subcontractor that specifies the subcontractor high level effort e^*. Following the standard mechanism in the literature of informal and relational contracting (see Bull (1987), Baker, Gibbons and Murphy (1994), Klein (1996) or

---

[8]Halac (2008) examines the role of relational contracting when information assymetries exist. In one of her extensions, the value of the relationships changes stochastically leaving unchanged the expected future value of the relationship. In our model, we will allow for exogenous changes in p (unexpected announcement regarding project availability in the future). This will not only change exogenously the value of z in immediate periods but also those of future periods since learning by doing will stop for a while.

Klein and Leffler (1981)[9]), the punishment mechanism enforcing this contract is the threat to end the relationship, which is valued by the subcontractor at $V(t')$.[10] There is no increase in disutility for effort e^* since the initial contract was already compensating this amount of effort and therefore the problem at hand is all based on the moral hazard on the subcontractor side.

In any given period t', the subcontractor will find optimal to exert e^* if

$$V(t') \geq \gamma_{ijtk}(0, n) - \gamma_{ijtk}(e^*, n), \tag{1}$$

or in other words, if the gain from shirking, $\gamma_{ijtk}(0) - \gamma_{ijtk}(e^*)$, is outweighed by the continuation value of the relationship, which depends on the surplus from future interactions and the discount rate of the subcontractor. Therefore, e becomes a function of V and ϕ_{i-jkt} such that $e = e(V, \phi_{i-jkt})$.

The cost to contractor i of subcontracting task 2 to subcontractor j is therefore

$$\widetilde{c}_{2kjt}(e) = \gamma_{ijt}(e(V, \phi_{i-jkt}), n) + c_{2kjt} + z_{kjt},$$

where z_t is the mark-up above cost on the task performed by subcontractor j and e is determined by evaluating (1). This mark-up is determined below in period 2.

4.2.2   Period 3: Maximizing Profits by Posting the Bid

Each contractor i in auction k chooses its bid to maximize expected profits:

$$\pi_{ikt} = (b_{ijkt} - c_{1kit} - \widetilde{c}_{2kjt}(e)) * \Pr(b_{ijkt} < b_{-ikt}).$$

The bid here is subscripted by j since the optimal bid will depend on which subcontractor is chosen in period 1. Denote the Bayes-Nash equilibrium strategy $b(c_{1kit}, \widetilde{c}_{2kjt})$. While we do not explicitly solve for the equilibrium of the auction game, the characteristics of the resulting equilibrium are well known in the literature. Bids are monotonically increasing in costs, and firm profits are decreasing

---

[9]In our setting, the provision of quality per se is not central and therefore we differ from the main purpose in Klein and Leffler (1981). Instead, the contractor cares about other aspects that are more generally referred as quality such as punctuality and thoroughness. The contractor here will combine the number of interactions and the "price" M such that the subcontractor does not find optimal to take away the maximal amount ϕ every time that they interact.

[10]For expositional purposes and simplicity we implicitly normalize the value of the contracting fallback option $V\prime$ to zero, though in reality this may not be necessarily optimal.

in costs.[11] For this reason, the subcontractor choices the firm makes in periods 1 and 2 are not affected by strategic bidding considerations – it will maximize profits to choose a subcontracting strategy that minimizes cost.

4.2.3 Period 2: Bargaining Between Contractor and Subcontractor

We now concentrate on the bargaining process that takes place between contractor i and each subcontractor j in period 2. From the start of this section, we assume perfect information between contractor and subcontractor regarding the cost to subcontractor j of producing task 2, c_{2kjt}, and the coordination cost γ_{ijkt} subject to the effort e^* exerted by subcontractor j.

In this stage, the contractor is simultaneously bargaining at no extra cost with all available subcontractors over the cost of providing task 2, and therefore it seems right to assume that all the bargaining power is on the contractor side. For this reason we take the total cost for contractor i to deal with subcontractor j the sum of the amount of the coordination and task costs plus the cost difference with the second cheapest subcontractor available to contractor i such that

$$\widetilde{c}_{2kjt}(e) = \gamma_{ijkt}(e, n) + c_{2kjt} + z_{kjt}.$$

4.2.4 Period 1: Contractor's Choice of Subcontractor

Finally, in period 1 the contractor decides what subcontractor to outsource task 2 to in order to maximize total expected profit. To do so, the contractor takes as given the mark-up in the bid originated in period 3 and the resulting level of $\widetilde{c}_{2kjt}$ in period 2 to make a choice in this period that maximizes its expected total profit.

In this case, contractor i will maximize its profit by solving the following problem

$$\max_{j \in J} \pi_{ijkt} = (b_{ijkt}(c_{1kit}, \widetilde{c}_{2kjt}(e(V, \phi_{i-jkt})))) - c_{1kit} - \widetilde{c}_{2kjt}(e(V, \phi_{i-jkt})) * \Pr(b_{ijkt}(c_{1kit}, \widetilde{c}_{2kjt}(e(V, \phi_{i-jkt}))) < b_{-ikt})$$

---

[11]It is worth noting that the equilibrium strategy will not be symmetric here even if firm costs are drawn independently and firms have access to the same subcontractors. This is because even *ex ante* identical firms will end up with different cost structures since a firm's cost in an auction depends in part the subcontractor coordination cost. As a firm works with a subcontractor, coordination costs go down by assumption in our model. Therefore, firms who happen to have favorable costs draws in the past, and therefore more past wins and subcontractor interactions, will have a lower cost of hiring subcontractors. Therefore, a more precise way to characterize the equilibrium strategy would be to describe it as conditional on coordination costs. However, we do not want to distract from the important point, unchanged by this consideration, that expected profits are higher for firms with lower cost, and therefore firms will choose the subcontractor that yields the lowest cost.

where

$$\widetilde{c}_{2kjt}(e(V, \phi_{i-jkt})) = \gamma_{ijtk}(e(V, \phi_{i-jkt}), n) + c_{2kjt} + z_{kjt}.$$

The contractor i then chooses subcontractor j of the J available to maximize its expected profit such that

$$j^* = \arg\max \pi_{ijkt}(b_{ijkt}, c_{1kit}, \widetilde{c}_{2kjt}(e(V, \phi_{i-jkt}), n), b_{-ikt}).$$

From this result, it is not difficult to see that the optimally chosen subcontractor j^* will likely have lower construction costs, more past interactions and higher value of future interactions than all the alternative subcontractors not chosen by contractor i.

4.3   Testable Implications

The toy model constructed above contains several testable predictions regarding the relation between the variables in the model in any given period t. The main predictions are the following:

- A contractor i will set a lower bid (and therefore will be more likely to win an auction) for a given project k when outsourcing to a subcontractor j for which construction and coordination costs $\gamma_{ijt}(e, n)$ are lower and the value of future interactions $V(t)$ is larger. And as a consequence,

- A contractor i will be more likely to choose for a given project k a subcontractor j for which construction and coordination costs $\gamma_{ijt}(e, n)$ are lower and the value of future interactions $V(t)$ larger.

To give these predictions empirical content, we start by discussing coordination costs relevant for the highway construction market. One well-established dimension driving differences in construction and coordination costs across contractor-subcontractor pairs is the geographic distance between the contractor, subcontractor, and project location. In particular, a contractor and subcontractor located close to each other geographically speaking will face lower coordination costs. We also expect that coordination costs will go down as a contractor and subcontractor interact more with each other, perhaps through match-specific learning-by-doing. We therefore form measures of the number of prior projects undertaken by a contractor with its subcontractors.

Our first testable implication that follows exploits past histories between a given pair of contractor and subcontractor: *The higher the number of bids won in the past jointly by a contractor and subcontractor, the lower the coordination costs and therefore the higher the likelihood that they will post a joint bid, and the lower the bid will be.* This testable implication goes through holding

constant the location of both contractor and subcontractor as well as all other dimensions relevant to the project.

Our second prediction is that situations in which the contractor is able to leverage the value of future interactions will induce the right amount of subcontractor effort, allowing the contractor to post a lower bid. We should observe that *the higher the number and value of (expected) future interactions, the higher the likelihood of posting a joint bid in the current period and the lower the bid will be (higher likelihood to win that auction).*

In the next section, we proceed to present the data and describe the empirical methodology that we use in this paper to test these implications.

5   Data Description

The data used in this study includes the universe of 5,120 road construction and repair contracts put up for bid by Caltrans between May 1996 and October 2005. For each contract up for bid, a set of information describing the project is given, including the road and county where the work will take place; a short description of the nature of work to be completed; the estimated number of working days to complete the project; and an engineer's estimate of the cost of completing the project. The engineer's estimate is formulated by Caltrans, and reflects project-specific factors incorporating past bids on similar projects. For every general contractor submitting a bid, the value of the bid and a list of first tier subcontractors is given.[12] Caltrans assigns a unique identifier to each firm, so it is possible to track prime contractors across contracts. In addition, we have assigned unique identifiers to subcontractors based on the firm name.[13] In all, we observe 26,125 bids from 1,735 different firms, of which 805 win at least one contract. These bids listed roughly 2,900 contractors.

It is worth mentioning a few of the drawbacks of the data. First, we only observe contracts administered by Caltrans and not those administered by local governments, which represent a significant fraction of the market. According to the 2002 Census of Governments, local governments in California expended $2.39 billion in capital outlay for highways compared to $2.99 billion for the state government. As a result, we will tend to understate the stock of relationships between

---

[12]A first tier subcontractor performs at least $10,000 or half of a percent of the contract, whichever is greater.

[13]Due to many small permutations of spellings for the same firm, these numbers were assigned by hand.

contractors and subcontractors, the extent of future opportunities, and the degree of project back-log. Furthermore, our data is truncated at May 1996, which indicates that we are not able to form measures of prior relationships and project backlog that include projects prior to this date. This problem is handled more easily, as we can control for the initial stock of relationships using firm fixed effects. Finally, even among the contracts in our data, we do not observe subcontractors to which only a small portion of the contract was awarded, nor do we know if subcontractors were switched out after the awarding of the project. The former is a problem depending on the form of the production function of relationships. If relationships are proportional to the intensity of utilization, then this is less of a problem than if relationships depend only whether or not two firms have interacted.

In Table 1 we present summary statistics of the data. In Panel A, we describe the characteristics of the auctions. The average auction has 5.15 participants, though this varies across auctions. The maximum number of bidders observed in the data is 30, though most auctions have fewer than eight bidders. The average engineer's estimate is $3.13 million, and there are significant differences in scale across projects. The engineer's estimate for the median project is only $620,000, and ranges from a low of $12,930 to a high of $800 million. This considerable variation in project scale is also reflected in the workdays the engineer anticipates will be required. The average working days are 163.4, while the median is only 70. The average project requires 34.8 items.

In Panel B, we describe characteristics of the observed bids. The average observed bid is $3.12 million, closely matching the average engineer's estimate. The average bid is nine percent above the engineer's estimate. While high bids are sometimes rejected for exceeding the engineer's estimate by more than ten percent, we still see some firms bidding substantially above the engineer's estimate, with the highest being 37 times greater. The average bidder lists 4.35 first tier subcontractors, with the most intensive user of subcontractors listing 38. Finally, we describe the experience of the typical firm and the average stock of relationships with subcontractors. The average bidder enters an auction having won 18 prior auctions, with the median bidder having won 4. The average bidder has used the subcontractors listed in the bid a total of 7.6 times on previous auctions won. This figure is particularly skewed, as the median bid involves only one prior subcontractor relationship while the max involves 404.

Panel C of Table 1 describes similar figures for the winning bidders. While the average bidder submitted a bid nine percent above the engineer's estimate, the average winner bid four percent

under the engineer's estimate. Bid winners do not appear more or less apt to subcontract, as they utilize virtually the same number of subcontractors as the broader population of bidders. They do tend to have significantly more experience, however, as the average winning bidder has won 26 prior auctions. They also have a higher stock of past interactions with the listed subcontractors, having used them 11.9 times on prior winning bids. This appears to be in large part due to these firms' greater number of past wins.

In the empirical models to follow, we will consider the entry and subcontractor utilization decisions of the largest firms in the industry. We limit that part of our analyses to the largest firms because we run into problems of degrees of freedom if including all participating bidders and because the actions of this sample of firms provide enough variation to examine the issues of our interest. We will also define the stock of relationships the firm has developed with subcontractors in a relevant geographic market. To better understand these aspects of the empirical work, we next describe the concentration of the market across firms and geographical areas.

In Table 2 we show the top twenty firms in terms of contracts won.[14] The industry is remarkably unconcentrated, with the largest 20 firms accounting for only 28 percent of contracts won. Granite Construction, to our knowledge the only publicly traded company in the data, wins the most auctions, capturing nearly eight percent of contracts. Considering market share based on winning bids, they won auctions worth $1.2 billion, or 7.5 percent of total awarded contract dollars. The next largest firm, Peterson Chase, won only 1.9 percent of contracts.

This lack of concentration in the Caltrans highway construction market masks a potentially significant geographic element. Firm costs have been found to rise significantly with distance (see for instance Bajari and Ye, 2003). We may expect that in a large state like California, relevant markets are more local. We consider a definition of the relevant market using Caltrans districts, of which there are 12. Figure 2 displays a map of the districts of California laid over the counties. Geographically, these districts are quite large. The most significant exception to this is Orange County which comprises a district of its own.

In Table 3, we present evidence regarding the degree to which firms operate within one district. In this table, we show the average number of wins of firms who win at least one contract and the

---

[14]We define market share based on the number of contracts won rather than on the dollar value of those contracts. We observe several joint ventures between firms that occur only once or very few times. We do not attempt to allocate market share between the firms in a joint venture, but we treat the joint venture as a separate firm. There are also a handful of very large large projects that significantly skew the data. In one instance, a firm won only one auction in the entire data for $1.4 billion, making them the largest firm in market share above Granite Construction, who won 407 auctions.

fraction of those wins that came in the firm's primary district.[15] We see that the average firm wins 6.4 auctions, 82 percent of which were in its primary district.   Since this may be skewed due to the significant fraction of firms that won only one contract, we also restrict attention to those firms that won more than one contract.   Of these firms, 69 percent of auction wins came from within the firm's primary district.

The subcontractor market surprisingly exhibits a similar degree of geographic concentration. Among subcontractors who appeared on at least one winning bid, the average subcontractor was utilized 9.5 times.   Of this utilization, 84 percent occurred within the subcontractor's primary district, almost identical to that observed for prime contractors. Similarly, if we restrict attention to firms that participate more than one time, 67 percent of utilizations occur within the primary district.   Subcontractors therefore seem to be geographically concentrated, and interestingly no more so than prime contractors.

6   Empirical Methodology and Results

6.1   Empirical Methodology

In this section, we describe the approach we will take to investigate the role of relationships between firms and their subcontractors.   We first need to define the two measures of relationships we will use.   We first consider the number of interactions a bidder had with those subcontractors listed in her bid on prior winning bids.   For the second measure, rather than listed subcontractors, we consider relevant subcontractors as those headquartered in the same Caltrans district as the current project.   The advantage of the first measure is that it focuses on the relationships with subcontractors most relevant for the current project. The second measure could also be justified. If a firm has a valuable relationship with a subcontractor in the district, yet a different subcontractor was chosen for the project, it reveals that the chosen subcontractor had some cost advantage on that particular contract. It is still the case, however, that the relationship has value, and that a firm with strong relationships within the district will on average have lower costs.

We then utilize these measures of the stock of past interactions with subcontractors, s_{ik}, for firm i on project k by estimating a regression of the form

$$y_{ik} = \beta_0 + \beta_1 log(1 + s_{ik}) + BX_{ik} + \phi_i + \epsilon_{ik} \tag{2}$$

---

[15]We define primary district here as the one in which the firm won the highest number of auctions.

where y_{ik} is the relevant outcome variable, either the log of the submitted bid or an entry indicator, X_{ik} is a vector of covariates, and ϕ_i is a contractor fixed effect. We add one prior to taking the log of the stock variable as a significant portion of its observations are zero. When investigating entry, we focus attention on the 20 largest firms in terms of auction participation, forming an auction participation indicator for each of these firms on each auction conducted in the sample.

The vector X_{ik} contains covariates describing project characteristics such as year and month effects, an engineer's estimate of project cost, the number of items required for the project, and the number of working days the project is likely to require. It also includes firm specific covariates that potentially vary across auctions, such as prior experience on projects in the area and an estimate of the firm's backlog of uncompleted projects.[16] Controlling for these variables is important. Since the subcontractor stock variable is based on subcontractor utilization on past *winning* projects, it will be directly correlated with the number of wins the firm has and with recently won contracts that are not yet completed. While the effect of experience on bids is mixed, firms have been found to bid higher when facing short run capacity constraints (see Jofre-Bonet and Pesendorfer, 2003).

Finally, the firm fixed effect potentially plays an important role. Our data is truncated at May of 1996, so it is not possible to measure firm interactions prior to this date. The initial stock of subcontractor interactions are captured in this fixed effect.

As already discussed, the coefficient β_1 should depend on the continuation value of relationships, since relational contracts must be self-enforcing. One approach to measuring the continuation value of a relationship at a given point in time would be to sum the value of future interactions between the contractor and subcontractor. While in many settings this may be the only available approach, it is problematic in that the degree to which a pair of firms works together depends on the quality of the match and would therefore be endogenous – a successful match would lead to both lower bids now and more interactions in the future.

Instead we use the total number of future contracts, f_{ik}, auctioned by Caltrans within a district. This measure will be correlated with the number of future contracts on which a contractor-subcontractor pair work together but is still uncorrelated with their specific productivity match since it is determined by district level transportation needs. We introduce this measure into the empirical specification by itself and also by interacting it with the firm's stock of prior interactions:

$$y_{ik} = \beta_0 + \beta_1 log(1 + s_{ik}) + \beta_2 log(1 + f_{ik}) * log(1 + s_{ik}) + \beta_3 log(1 + f_{ik}) + BX_{ik} + \phi_i + \epsilon_{ik}. \quad (3)$$

---

[16]We measure backlog by the fraction of the dollar value of outstanding projects that are not yet completed. To obtain this measure, we assume that projects are completed linearly by day, that the firm begins work on the project award date, and that the firm takes the estimated working days to complete a project it has won.

To account for forward looking bidders who rationally anticipate future capacity constraints brought on by winning the current auction, we only consider those future projects occurring after the anticipated completion of the current project. Our primary coefficient of interest will be β_2, which describes how the value of relationships depends on future contracting opportunities.

Controlling directly for future contract volume (coefficient β_3) accounts for several possible confounding factors. First, anticipated future contract opportunities may invite market entry, which could lower prices in the market for subcontractors. Second, if learning by doing is important, then the effect of learning on future costs will be in part priced into the current bid. In a period of high anticipated contract volume, there is incentive to win contracts now so that the firm will have a lower cost for future contracts. Nevertheless, the current shadow price of capital may increase and therefore current bids may increase. Overall, the direct effect is ambiguous.

According to our testable implications regarding coordination costs and the future value of interactions, past interactions lower coordination costs ($\beta_1 < 0$). Moreover, contractors may only profit from lower coordination costs due to past interactions if there are future interactions at stake ($\beta_2 < 0$). Predictions regarding the direct effect of future value of interactions (β_3) are ambiguous.

6.2 Results

6.3 Firm bidding

We begin by presenting the results documenting the correlation between the stock of subcontractor relationships and bidding behavior. In Table 5, we present estimates of (2) using as a measure of relationships the prior interactions with subcontractors listed in the current bid. In column 1 we find a significant negative relationship between the stock of interactions and the bid a firm submits. This beneficial effect on the firm's bid holds up after controlling for bidder fixed effects in column 2. This result is consistent with the existence of learning by doing and our first testable implications that a higher number of past interactions between contractor and subcontractor will lower the bids. Similarly, note that the total number of projects in which a contractor has worked in the past is negatively correlated with the bid posted. This result is also consistent with general (non-specific) learning by doing on the contractor side. The other covariates we consider are largely consistent with the prior literature on the highway construction market. Backlog is associated with higher bids, consistent with the presence of short-run capacity constraints. Also, competition lowers prices, as each opposing bidder reduces the firm's bid by around one percent. We also find that while

past wins are positively associated with bids, past wins within the project county are negatively associated with bids.

In column 3 of Table 5, we examine whether the age of the relationship matters by separating past interactions occurring within the past year into three month intervals, and also separately considering those contractor-subcontractor interactions occurring more than one year prior to the auction date. We find that our initial results are driven by interactions occurring at least nine months prior, suggesting that more established relationships are more important than recent interactions with subcontractors.

In columns 4 and 5 of Table 5, we consider the interaction of the stock of relationships with the degree of future contracting opportunities in the project district. We consider separately the number of future contracts and the dollar value of these contracts. We find that both more future contracts and more future contract dollars increase the value of the stock of relationships. Interestingly, when this interaction is included in the specification, the main effect of the relationship stock variable is cut in magnitude by at least one-half and becomes statistically indistinguishable from zero. This suggests that relationships have little value when the continuation value of the relationship is zero. This result is consistent with our testable implications and in general with implications from the relational contracting literature. The coefficients of all the other covariates remain unchanged and statistically significant to including the number and value of future interactions.

In Table 4, we present similar estimates using an alternative measure of the stock of relationships, past interactions with the subcontractors whose headquarters are within the project district. We obtain results that are very similar to those using the first measure of the stock of relationships. We again find that firms with more relationships bid lower, and that the beneficial effect of relationships is greater as there is a greater degree of future potential business. Again, without the self-enforcement mechanism of future business, past relationships seem to have little effect on their own. All other controls used in the specifications presented in Table 4 have the same qualitative effect on the dependent variable as they did in Table 5.

Timing of future contracts

One may worry that our measures of future business volume may capture unobserved differences between high- and low-volume areas that are correlated with more aggressive bidding but have nothing to do with the self-enforcing informal agreement between contractor and subcontractor.

One way to address this concern is to consider the timing of the arrival of future contracts. The timing of the arrival of projects is relevant for self-enforcing agreements since there is less advance knowledge of projects in the distant future. Also, discounting makes these projects less important in the continuation value of the relationship, and there is also an element of uncertainty regarding how the contractor-subcontractor relationship will evolve in the intervening time.

In Table 6, we present the results of estimating specifications where we distinguish future contracts taking place within one year of the current period from those taking place between one and two years from the current period. Our results show that only the number and volume of future contracts within a year of the current period matters and lowers the current bid of contractors. The fact that future contracts that are further away in time do not matter is not surprising since contractors and subcontractors are less likely to be aware of their existence so far in advance and shows that there is no underlying correlation across periods and districts driving our results in Tables 4 and 5.

Relationship depth

Thus far, our results do not shed light on the role of the depth of relationships between contractors and subcontractors. The two measures of subcontractor relationships do not distinguish between contractors who have developed a deeper relationship with a particular subcontractor from contractors whose relationships are spread more evenly across subcontractors. To investigate the role of relationship depth, we consider how unequally distributed a firm's interactions are across its subcontractors. For this purpose, we examine the share of a contractor's subcontractor interactions in a district that are held with its most used subcontractor.[17] Conditional on the total stock of relationships, this measure will indicate whether it is more valuable to concentrate these relationships among a few suppliers or spread them among many suppliers. We then form a triple interaction between this variable, the firm's total stock of relationships, and future business opportunities. From this, we can tell whether the self-enforcement value of future business is more important for deeper relationships.

We show our results in Table 7. These results suggest that the stock of prior relationships is more valuable when concentrated in one subcontractor. However, concentrating in one supplier

---

[17]While our primary measure of a firm's relationship to this point has been the contractor's interaction with the subcontractors listed in its bid, in this case it is more sensible to use the overall relationships with subcontractors in the district. If we were to instead use listed subcontractors, the measure would have less meaning since there are generally only a handful of listed subcontractors.

does not increase the importance of future business opportunities. This is true whether future business opportunities are measured using the number of contracts or their dollar value. This may suggest that concentrating in a few suppliers may lower bids through lower coordination costs, while relationship depth is not important for self-enforcing informal contracts.

6.4 Participation decision

Next we consider the role of subcontractor relationships in the entry decision for the twenty largest firms in the industry, as defined by those firms participating in the most auctions. For each auction, we form twenty observations indicating whether each firm participates in the auction. We again form measures of the stock of each firm's subcontractor relationships in the project district.[18]

Table 8 presents the results of regressing the participation indicator on the measure of the stock of subcontractor relationships. Consistent with the bidding results in previous tables, results in columns 1 and 2 show that entry becomes more attractive as the relationship stock goes up. In contrast with the results from the specification of bids, more recent interactions have a stronger impact on entry than do older interactions (see column 3). Finally, the impact of relationships again depends on their continuation value, as the interaction of relationships and future contracts is positively related to entry while in this case the direct effect of relationships is actually negative. These results are robust to the introduction of bidder fixed effects and the covariates used in previous tables.

6.5 Subcontractor utilization decision

Lastly, Table 9 analyzes the subcontractor choice by a contractor for a given project. As with the specifications we display in Table 8, we limit our sample here to the 20 largest contractors in our sample. We consider all subcontractors that each one of these large contractors has ever listed during our sample period. We then form a dummy variable indicating whether firm i used subcontractor j on the particular auction k. We then regress this utilization dummy on the stock of prior relationships between the two firms, and as before we also consider an interaction between this measure and future contract opportunities within the project district.[19]

---

[18]It is not possible to measure interactions with listed subcontractors, as this is only observed for participating firms.

[19]Subcontractor choice is not independent since if a firm is using one subcontractor to complete a task it is not using another. Subcontractor choice is also unlikely to be independent across bidders within the same project since some subcontractors will have unobserved cost advantages. For these reasons, we adjust the standard errors for clustering at the contract level.

One concern with this specification is the fact that subcontractors are chosen in the basis of lower joint construction and coordination costs. Since we do not observe construction costs if these are correlated with coordination costs and therefore with relationship stocks, we may obtain biased estimates of the effect of past interactions on subcontractor utilization. To address this, we control for two variables that reflect subcontractor cost. One is an indicator of whether other bidders also use the same subcontractor, which captures the otherwise hidden subcontractor cost advantage. The other is an indicator of whether the project takes place on the subcontractor's primary district. Since distance is an important determinant of a firm's cost in this industry, subcontractors located near the project will have a cost advantage.

Our results are presented in Table 9. Subcontractors with whom the contractor has an existing relationship are more likely to be chosen. Furthermore, this becomes even more true as future business opportunities, as measured by the number of contracts, increases. In contrast to our prior results, this does not hold true when future opportunities are measured by contract dollars. As expected, the bidder is more likely to use a particular subcontractor if other firms in the same auction are using that same subcontractor. Also, firms are more likely to choose subcontractors located in the same district of the project.

7   Conclusions

In this paper we have examined how relationships between contractors and subcontractors influence bidding behavior and participation decisions of contractors in California highway procurement auctions. We present a simple model that yields two main testable implications. First, contractors with a bigger stock of past interactions with their subcontractors should be able to post lower bids (due to lower coordination costs) that eventually allows them to win more auctions. Second, contractors with a potentially higher number of future interactions with their subcontractors should be able to post lower bids (due to better mitigation of moral hazard problems) and therefore be more likely to win the auction at stake.

Our results provide support for our predictions. First, we find that a higher number of past interactions is correlated with lower posted bids. Second, we find that a higher number of future potential contracts in the contractor and subcontractors' Caltrans district is also correlated with lower posted bids. Moreover we find that the interaction between past interactions and future potential interactions is not only strongly correlated with lower posted bids but it also wipes out

23

the direct effect of past interactions. We also examine the effect of past and future interactions on auction participation and subcontractor choice and find qualitatively similar results. These findings imply that firms are only able to use gains from repeated past interactions when future business opportunities are present.

This result is important and constitutes the main contribution of this research for two main reasons. Prior empirical literature in relational contracting has tended to use past interactions as a proxy for future interactions. Our result here demonstrates that such strategy could lead to potentially wrong conclusions. Our result is also important because it is, to our knowledge, the first test the importance of the relationship continuation value.

As we empirically examined in this paper the impact of past and future interactions on bidding behavior, auction participation and subcontractor choice, future research could extend the present work to study the efficiency implications of these effects. Specifically, gains from past and future interactions may drive contractors to choose subcontractors with not the lowest task production costs. This may increase overall construction costs if more efficient subcontractors are passed over due to a lack stock of past relationships.

Panel A describes the summary statistics of 5120 contracts awarded by Caltrans from May 1996 through October 2005, nearly all contracts awarded during this time. The number of items reflects how many distinct items are listed on the contract. The workdays variable measures the engineer's evaluation of the time to completion in days. Panel B provides information on the 25631 bids observed on these auctions. Panel C provides information on the bids that won the 5120 auctions.

The set of prime contractors includes all those firms that were observed winning at least one Caltrans contract between May 1996 and October 2005. Total wins describes the number of times in the sample a firm won an auction. The variable "In primary district" describes the fraction of these wins in that occurred in the district where the firm won the most auctions. The sample is further narrowed down to include only those firms that won more than won auction. For subcontractors, we count the number of times the firm appeared as a subcontractor on a winning bid, and the fraction of those appearances that occurred in the district where the firm had the most appearances.

The dependent variable is the log of the firm's bid. The stock of subcontractors is the sum of the firm's prior interactions on winning bids with subcontractors listed in the firm's bid. Future contract dollars in district is the sum of the engineer's estimate for all projects occurring in the next 360 days in the project's district. One has been added to each variable for which logs were taken, except for the number of items and the engineer's estimate, to deal with missing values.

Standard errors corrected for clustering by contract are in parenthesis.

*,**,*** denote significance at the 90%, 95%, and 99% level, respectively.

The dependent variable is the log of the firm's bid. The stock of subcontractors is the sum of the firm's prior interactions on winning bids with subcontractors headquartered in the project district. Future contract dollars in district is the sum of the engineer's estimate for all projects occurring in the next 360 days in the project's district. One has been added to each variable for which logs were taken, except for the number of items and the engineer's estimate, to deal with missing values.

Standard errors corrected for clustering by contract are in parenthesis.

*,**,*** denote significance at the 90%, 95%, and 99% level, respectively.

The dependent variable is the log of the firm's bid. The stock of subcontractors measure used in specifications (1) and (2) is the sum of the firm's prior interactions on winning bids in the same district as the current project. The stock of subcontractors measure used in specifications (3) and (4) is the sum of the firm's prior interactions on winning bids with subcontractors listed by the firm on the current project. Future contract dollars in district is the sum of the engineer's estimate for all projects occurring either within one year or between one and two years in the project's district. One has been added to each variable for which logs were taken, except for the number of items and the engineer's estimate, to deal with missing values. Other covariates included in the specifications match those described in Table 5.

Standard errors corrected for clustering by contract are in parenthesis.

*,**,*** denote significance at the 90%, 95%, and 99% level, respectively.

The dependent variable is the log of the firm's bid. The stock of subcontractors is the sum of the firm's prior interactions on winning bids in the same district as the current project. The top subcontractor share is the fraction of the firm's relationship stock concentrated in its most frequently used subcontractor. Future contract dollars in district is the sum of the engineer's estimate for all projects occurring in the next 360 days in the project's district. One has been added to each variable for which logs were taken, except for the number of items and the engineer's estimate, to deal with missing values. Other covariates included in the specifications match those described in Table 5.

Standard errors corrected for clustering by contract are in parenthesis.

*,**,*** denote significance at the 90%, 95%, and 99% level, respectively.

The dependent variable is an indicator for whether a particular subcontractor was used by the contractor on that particular auction. The sample includes the 20 largest firms in terms of auction participation. The stock of prior interactions represents the number of times the contractor has worked with that particular subcontractor on prior winning contracts. Future contract dollars in district is the sum of the engineer's estimate for all projects occurring in the next 360 days in the project's district. One has been added to each variable for which logs were taken, except for the number of items and the engineer's estimate, to deal with missing values.

All specifications include controls for year and firm effects, and columns 2-4 contain controls for month dummies. Standard errors corrected for clustering by contract are in parenthesis.

*,**,*** denote significance at the 90%, 95%, and 99% level, respectively.
